

POSTMORTEM: INCIDENT #SEC-2026-0419

Incident Severity: P1 (High) | **Lead Responder:** Jason Morales, Staff Security Engineer

Date of Occurrence: February 12, 2026 03:14 UTC | **Resolved:** February 12, 2026 05:42 UTC (Total Duration: 2h 28m)

1. Incident Summary

At 03:14 UTC, our automated canary alerts flagged anomalous spikes in egress network bandwidth originating from worker node worker-gpu-08. Analysis revealed an unauthorized external DNS exfiltration attempt caused by a compromised dependency package 'pdf-formatter-core' v1.2.8.

2. Root Cause Analysis

A typosquatted malicious dependency was inadvertently merged during an unpinned lockfile update. The malicious payload attempted to transmit environment variable secrets via base64 DNS tunneling to an external command-and-control server (c2.shadow-network.org).

3. Impact Assessment

- Vector Store Data: No breach. Vector endpoints were isolated behind private VPC subnets.
- Customer Documents: 0 documents accessed. Egress firewalls blocked 99.4% of outbound requests.
- Credentials Affected: A staging Supabase service key was rotated immediately as a defensive measure.

4. Corrective & Preventative Actions

1. Implemented strict hash-pinned software bills of materials (SBOM) across all CI/CD pipelines.
2. Deployed eBPF-based runtime syscall enforcement to terminate unexpected socket connections instantaneously.
3. Mandated multi-party code reviews for any dependency version alterations in requirements.txt.
